

CS-225: Discrete Structures in CS

Homework 3, Part 1

Noah Hinojos

January 28, 2024

Exercise Set 4.7

18

Suppositions: Suppose not. Let a be a rational number, b be a non-zero rational number, and r be an irrational number. If this is so, then $a + br$ must be an rational number.

Goal:

We must arrive at a contradiction.

Deductions:

$r = \frac{fgd-fch}{edh}$ where c and g are integers; and d, e, f , and h are non-zero integers.:

- By definition of rational, $a = \frac{c}{d}$ where c, d are integers and $d \neq 0$.
- By definition of rational, $b = \frac{e}{f}$ where e, f are integers and $f \neq 0$.
- Through algebra, $b \neq 0 \Rightarrow \frac{e}{f} \neq 0 \Rightarrow e \neq 0$
- By definition of rational, $a + br = \frac{g}{h}$ where g, h are integers and $h \neq 0$.

- By substitution, r can be represented as follows:

$$\begin{aligned}
a + br &= \frac{g}{h} \\
\left(\frac{c}{d}\right) + \left(\frac{e}{f}\right)r &= \frac{g}{h} \\
\frac{c}{d} + \left(\frac{e}{f}\right)r &= \frac{g}{h} \\
\left(\frac{e}{f}\right)r &= \frac{g}{h} - \frac{c}{d} \\
r &= \left(\frac{f}{e}\right)\left(\frac{g}{h} - \frac{c}{d}\right) \\
&= \frac{fg}{eh} - \frac{fc}{ed} \\
&= \frac{fgd}{ehd} - \frac{fch}{edh} \\
&= \frac{fgd - fch}{edh}
\end{aligned}$$

- Hence $r = \frac{fgd-fch}{edh}$.

The product of three integers is an integer:

- Let x , y , and z be some integers.
- Then their product is xyz .
- Let $w = xy$.
- Due to closure, w is an integer because it is the product of two integers.
- Let $v = wz$.
- $v = xyz = wz$.
- Due to closure, v is an integer because it is the product of two integers.
- Since $xyz = v$, xyz is also an integer.
- Hence, the product of three integers is an integer.

The product of three non-zero integers is a non-zero integer:

- Let i , t , and u be some non-zero integers.
- Then their product is stu .

- Let $p = st$.
- Due to closure and zero product property, p is a non-zero integer because it is the product of two non-zero integers.
- Let $q = stu$.
- $q = stu = pu$.
- Due to closure and zero product property, q is a non-zero integer because it is the product of two non-zero integers.
- Since $stu = q$, stu is also a non-zero integer.
- Hence, the product of three non-zero integers is a non-zero integer.

r is rational:

- Recall $r = \frac{fgd-fch}{edh}$.
- Let $i = fgd$.
- i is an integer because it is the product of three integers.
- Let $j = fch$.
- j is an integer because it is the product of three integers.
- Let $k = edh$.
- k is a non-zero integer because it is the product of three non-zero integers.
- $r = \frac{fgd-fch}{edh} = \frac{i-j}{k}$.
- Let $l = i - j$.
- Due to closure, l is an integer because it is the difference of two integers.
- $r = \frac{i-j}{k} = \frac{l}{k}$.
- By definition of rational, r is a rational number because it can be expressed as $\frac{l}{k}$ where l is an integer and k is a non-zero integer.

We arrived at a contradiction because r is rational. This contradicts the supposition that r is irrational.

Conclusion:

Therefore, it must be true that if a and b are rational numbers, $b \neq 0$, and r is an irrational number, then $a + br$ is irrational.

Suppositions:

Suppose not. Let's assume there exists positive real numbers r and s and $\sqrt{r+s} = \sqrt{r} + \sqrt{s}$

Goal:

Arrive at contradiction.

Deductions:

For any positive real number a , \sqrt{a} is a non-zero real number:

- Let $\sqrt{a} = b$
- $\sqrt{a} = b \Rightarrow b^2 = a$
- By equality, b^2 is a positive real number because a is a positive real number.
- By zero product property, b is a non zero real number because b^2 is a non-zero real number.
- By equality, \sqrt{a} is a non-zero real number because b is a non-zero real number.

The product of any three non-zero real numbers is a non-zero real number:

- Let x , y , and z be non-zero real numbers.
- Then their product is xyz .
- Let $w = xy$.
- Due to zero product property, w is a non-zero real number.
- Let $v = xyz$.
- $v = xyz = wz$.
- Due to zero product property, v is a non-zero real number.
- Since $xyz = v$, xyz is also a non-zero real number.
- Hence, the product of three non-zero real numbers xyz is a non-zero real number.

$$\sqrt{r+s} = \sqrt{r} + \sqrt{s} \Rightarrow 0 = 2\sqrt{r}\sqrt{s}.$$

$$\begin{aligned}\sqrt{r+s} &= \sqrt{r} + \sqrt{s} \\ r+s &= (\sqrt{r} + \sqrt{s})^2 \\ r+s &= r + 2\sqrt{r}\sqrt{s} + s \\ 0 &= 2\sqrt{r}\sqrt{s}\end{aligned}$$

If r and s are positive real numbers, then $2\sqrt{r}\sqrt{s} \neq 0$.

- \sqrt{r} is a non-zero real number since r is a positive real number, as shown before.
- \sqrt{s} is a non-zero real number since s is a positive real number, as shown before.
- $2\sqrt{r}\sqrt{s}$ must be a non-zero real number because it is the product of three non-zero real numbers, as shown before.
- Hence $2\sqrt{r}\sqrt{s} \neq 0$.

The supposition is contradictory because the supposed equation requires $0 = 2\sqrt{r}\sqrt{s}$ to also be true. However, $2\sqrt{r}\sqrt{s} \neq 0$ because r and s are positive real integers.

Conclusion:

Therefore, for all positive real numbers r and s , $\sqrt{r+s} \neq \sqrt{r} + \sqrt{s}$ must be true.

4.8

18 - a

Suppositions:

Suppose a is not even, hence it is odd.

Goal:

Prove a^3 is odd.

Deductions:

The product of two odd integers is odd:

- Let the product of two odd integers be xy where x and y are odd integers.
- By definition of odd, $x = 2s + 1$ and $y = 2t + 1$ where s and t are some integers.

- By algebra, xy can be rewritten:

$$\begin{aligned} xy &= (2s + 1)(2t + 1) \\ &= 4st + 2s + 2t + 1 \\ &= 2(2st + s + t) + 1 \end{aligned}$$

- Let $n = st$.
 - By closure, n is an integer because it is the product of two integers.
 - Let $w = 2st$.
 - $w = 2st = 2n$.
 - By closure, w is an integer because it is the product of two integers.
 - Let $z = s + t$.
 - By closure, z is an integer because it is the sum of two integers.
 - Let $v = st + s + t$.
 - $v = st + s + t = w + z$.
 - By closure, v is an integer because it is the sum of two integers.
 - Let $t = xy$.
 - $t = xy = 2(st + s + t) + 1 = 2v + 1$.
 - By definition of odd, t is an odd integer.
 - By equality, xy is an odd integer since t is an odd integer.
 - Therefore, the product of two odd integers is an odd integer.
- a^3 is an odd integer:
- Let $b = a^2$.
 - Since b is the product of two odd integers, b is an odd integer, as shown before.
 - Let $c = ab$.
 - Since c is the product of two odd integers, c is an odd integer, as shown before.
 - $c = ab = a(a^2) = a^3$
 - By equality, a^3 is an odd integer because c is an odd integer.

Thus, a^3 was shown to be an odd integer because a is an odd integer.

Conclusion:

For every integer a , if a^3 is even then a is even.

18 - b

Suppositions:

Suppose not. Let's assume $\sqrt[3]{2} = p$ and p is a rational number.

Goal:

Arrive at a contradiction.

Deductions:

p is not rational:

- This will be proven by proof of contradiction.
- Suppose p is rational. If this is contradictory, then p must be irrational.
- By definition of rational, $p = \frac{a}{b}$ where a is an integer and b is a non-zero integer.
- This implies a and b also have no common factors.
- By algebra,

$$\begin{aligned}p &= \sqrt[3]{2} = \frac{a}{b} \\ \sqrt[3]{2} &= \frac{a}{b} \\ 2 &= \frac{a^3}{b^3} \\ 2b^3 &= a^3\end{aligned}$$

- Let $n = b^3$.
- n is an integer because it is the product of three integers (See Exercise Set 4.7 #18 above).
- Let $m = 2b^3$.
- $m = 2b^3 = 2n$.
- By definition of even, m is an even integer.
- $a^3 = 2b^3 = m$.
- By definition of even, a^3 is an even integer. Therefore, a must also be even.
- Then $a = 2n$ where n is an integer.
- $2b^3 = a^3 = (2n)^3 = 2 \cdot 2^2 \cdot n^3 = 2(4n^3)$
- Let $o = n^3$.

- o is an integer because it is the product of three integers (See Exercise Set 4.7 #18 above).
- Let $k = 2n^3$.
- $k = 2n^3 = 2o$.
- By definition of even, k is an even integer.
- Let $j = 4n^3$.
- $j = 4n^3 = 2k$.
- By definition of even, j is an even integer.
- $2b^3 = 2(4n^3) = 2j$
- $b^3 = j$
- By definition of even, b^3 is an even integer. Therefore, b must also be even.
- Since a and b are even, they have a common factor of 2.
- However, this contradicts the prior deduction that a and b must have no common factors.
- Therefore, the supposition p is rational is contradictory.
- Hence, p must be irrational.

Conclusion:

$\sqrt[3]{2}$ is irrational.
